Week8 Cache Intro

Wednesday, July 27, 2022 11:14

0. Cache introduction

0.1. Intuitions: Take advantage of locality

- Temporal Locality
 - o If a memory location is **referenced** then it **will tend to be referenced again soon**
 - => Then we keep the most recently accessed data items closer to the processor
- Spatial Locality
 - olumnate is necessarily location is referenced, the locations with nearby addresses will tend to be referenced soon
 - => Move blocks consisting of contiguous words closer to the processor

Therefore, we tend to do the following

- Temporal: The data we access is saved in the cache for potential future use
- Spatial: We bring in a chunk of data at a time because there is a good chance that we will want to access other data within the chunk

Consider the following load word instruction

- Instruction: Iw t0, 0(t1)
 - Say t1 contains 0x12F0, Memory[0x12F0] = 99

0.2. Comparing memory access with / without cache

Without cache

- 1. Processor issues address 0x12F0 to memory
- 2. Memory reads word at address 0x12F0, *(0x12F0) = 99
- 3. Memory sends 99 to processor
- 4. Processor loads 99 into register t0

With cache

- 1. Cache checks to see if has copy of data at address 0x12F0
 - a. If finds a match (Hit): cache reads 99, sends to processor
 - b. If not (Miss): cache sends address 0x12F0 to memory
 - i. Memory reads 99 at address 0x12F0
 - ii. Memory sends 99 to cache
 - iii. Cache replaces word which can store at address 0x12F0 with 99
 - iv. Sends 99 to processor
- 2. Processor loads 99 into register t0

2. Fully associative cache

0. Terminologies

- Cache line/block: A single entry in the cache
- Line size / block size: The number of bytes in each cache line
- Tag: Identifies the data stored at a given cache line
- Valid bit: Tells if data stored in a given cache line is valid
- Capacity: The total number of data bytes that can be stored in a cache

1. Address partition for fully associative cache

Only two fields in address: Tag for searching word, and byte offset for byte

- # of byte offset bits = log(linesize)
- # tag bits = # address bits # offset bits

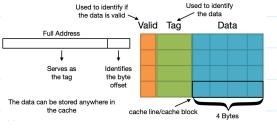

2. Eviction Policies

When cache is full, the least recently used entry will be evicted, and be overwritten with new information Least-Recently Used (LRU)

- Hardware keeps track of access history
- Replace the entry that has not been used for the longest time
- 3. Handling Stores (Write policy)
- Store instructions will write to memory and change values
- We must make sure cache and memory have consistent information
 Write-through / Write-back policies
- Write-through
 - Write to the cache and the memory at the same time
 - Pros: Simple to implement
 - Cons: Write to memory will take longer, and increase the traffic to the memory
- Write-back
 - $\circ\quad$ Write data in caches, and set the dirty bit to 1
 - o When this line gets evicted from the cache, write it to memory
 - Pros: Lower traffic to memory, because you may write to something multiple times before you evict it from the cache
 - Cons: Additional control logics

Step by step demo: Assuming 12-bit width address

1. Load word at 0x5E0

Valid Tag

Data

Cons: Additional control logics

Step by step demo: Assuming 12-bit width address

1. Load word at 0x5E0

Address partitioning

0x5E0 = 12'b0101 1110 0000:

where tag = 10'b01 0111 1000 = 0x178, byte offset = 2'b00, loading the **entire cache** line *Check hit/miss*

Tag Hits 0x178, Load the word in entry 0x178 (LRU is also updated)

2. Load word at 0x524

Address partitioning

0x524 = 12'b0101 0010 0100:

Where tag = 10'b01 0100 1001 = 0x149, byte offset = 2'b00, loading the **entire cache line** *Check hit/miss*

Tag misses, we don't have that data. Place the loaded data into cache line with tag=0x149

3. Load byte at 0x972 (Take LRUs into consideration)

Address partitioning

0x972 = 12'b1001 0111 0010:

Where tag = 10'b10 0101 1100 =0x25C, byte offset = 2'b10 = 0x2, load byte = 2'b10 Check hit/miss

- Tag misses, and cache is full. Evict the LRU cache line with LRU=3
- Then place tag = 0x25C at the cache line where LRU was 3
 Update LRUs

Update LRU fields:

- LRU of newly placed content is set to 0
- · Update all of their LRUs accordingly

Then we are going to store byte at 0x524, take write policies into consideration

4. Store byte at 0x524

Address partitioning

0x524 = 12'b0101 0010 0100:

Where tag = 10'b01 0100 1001 = 0x149, byte offset = 2'b00, loading the **entire cache line** Check hit/miss

Tag hit, we have the data in cache, but we will write this piece of cache Update LRUs

Cache line with tag = 0x149 is updated and be the MRU, set it to 0

Assuming Write-back policy in this cache

Set dirty bit to 1, indicating we have write the cache, but not write the memory yet

Conclusion for Fully associative cache

Data can be stored anywhere in the cache, Search/place data only using the **tag field in address Pros:**

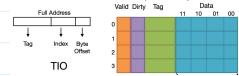

- Flexibility of placing memory block in any cache line, and fully utilize the cache
- Full utilization offers better hit rate
- · Flexibility of various replacement algorithms

Cons:

- Complexity make it slow, large, and power-consuming
- · As each entry requires a comparator to check the tag

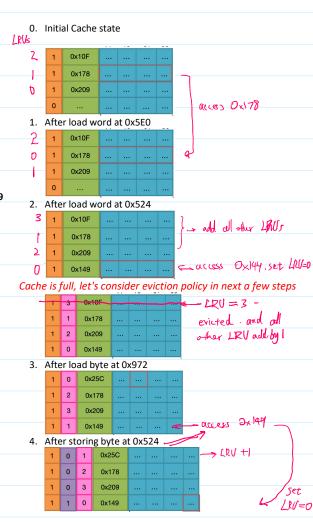

3. Direct Mapped Caches

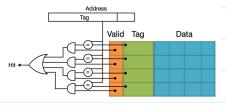

The data can ONLY be stored in one location: which is specified by the index field in address

1. Address partitioning for Direct mapped cache

- # byte offset bits = log2(line size) => for 4 byte word: # offset bits = log2(4) = 2
- # index bits = log2(# of cache lines) => for this example, a 4 entry cache: #index bits = log2(4) = 2
- # tag bits = # addr bits # index bits # offset bits
- Note that byte offset bits can be larger, assume line size is 4-words, 16 bytes, then # offset bits = log2(16) = 4
 - In this case, as a word is still 4 byte, only 2 bits needed for byte offset, then the upper 2 bits is actually the word offset

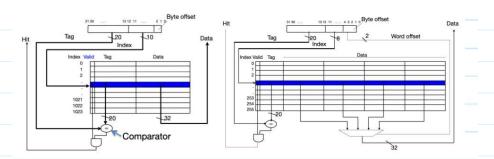

Example for direct mapped cache:

LHS: 1 word blocks, 4KB data

RHS: 16 Byte (4 word) block size, 4KB data

2. Step by step demo: Direct mapped cache

Load byte at 0xFE2

Address partitioning

0xFE2 = 12'b1111 1110 0010:

where tag = $8'b1111\ 1110 = 0xFE$; index = 2'b00; byte offset = 2'b10

Check hit/miss?

Of course we get a miss here, bring the entire line into entry with index=2'b00

2. Load byte at 0xFE8 and then load 0xFE9

a. Load 0xFE8

Address partitioning

0xFE2 = 12'b1111 1110 1000:

where tag = $8'b1111\ 1110 = 0xFE$; index = 2'b10; byte offset = 2'b10

Check hit/miss?

Of course we get a miss here, bring the entire line into entry with index=2'b10

b. Load 0xFE9

Address partitioning

0xFE2 = 12'b1111 1110 1001:

where tag = 8'b1111 1110 = 0xFE; index = 2'b10; byte offset = 2'b11

We have load contents into index 2'b10, and tag matches, we get a hit. Then load byte from byte=2'b11

Here, we need to consider Direct mapped cache replacement

Some cache line might be replaced then

3. Load byte at 0xDF9

Address partitioning

0xDF9 = 12'b1101 1111 1001:

where tag = $8'b1111\ 1110 = 0xDF$; index = 2'b10; byte offset = 2'b01

Check hit/miss?

Valid at entry 2'b10 but Tag doesn't match, it's a miss. The entire cache line will be evicted,

Next the word from 0xDF8 will be placed in entry with index =2'b10

4. Load byte at 0xFE8

Address partitioning

0xDF9 = 12'b1111 1110 1000:

where tag = $8'b1111\ 1110 = 0xFE$; index = 2'b10; byte offset = 2'b00

Check hit/miss?

Valid at entry 2'b10 but Tag doesn't match, it's still a miss. The entire cache line will be evicted,

Next the word from 0xFE8 will be placed in entry with index =2'b10

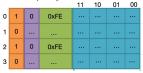

Conclusion for Direct Mapped Cache

Different from fully associate cache, data can only be stored at the certain entry (Cache line) As the address partitioning has: Tag, index, and offsets. Index will constrain where to store the data

- Pros: Cheap and fast from the perspective of circuit design
- Cons:
 - o More likely to have cache conflict's, and higher miss rates
 - o No flexibility of replacement algorithm

0. Initial State 3 0 1. After Load 0xFE2 0

2. After load 0xFE8 and Trying to load 0xFE9

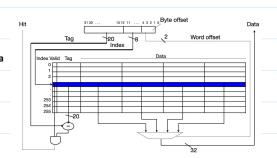

3. After Load byte at 0xDF9

0	1	0	0xFE	 	
1	0			 	
2	1	0	0xDF	 	
3	0			 	

4 After load byte at OvEER

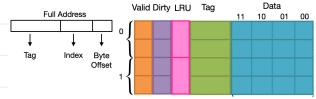

4. Aitel load byte at on Lo							
				11	10	01	0
0	1	0	0xFE				
1	0						
2	1	0	0xFE				
3	0						

4. Set-Associative Caches

A combination of two types of caches. In fact, we get multiple "associative" caches, each is labeled with a certain index

. The data can only be stored at one index, but there are multiple slots to store it in

1. Address partitioning for Set-Associative Caches

Partition is similar to direct mapped cache, the ONLY difference is the index field. Index is an index of sets

- # byte offset bits = log2(line size) => for line size that just fits a 4 byte word: # offset bits = log2(4) = 2
- # index bits = log2(# of cache lines) => for this example, a 2 set set-associative cache: # index bits = log2(2) = 1
- # tag bits = # addr bits # index bits # offset bits => In this example, # tag bits = 12 2 1 = 9

2. Step by step demo: Direct mapped cache

1. Load byte at 0x8E2

Address partitioning

0xFE2 = 12'b1000 1110 0010:

where tag = 9'b1 0001 1100 = 0x11C; index = 1'b0; byte offset = 2'b10

Check hit/miss?

Of course we get a miss here, bring the entire line into the first empty entry with index=1'b0

2. Load byte at 0x8E8 and then load 0x8E9

a. Load 0x8E8

Address partitionina

0xFE2 = 12'b1000 1110 1000:

where tag = $9'b1\ 0001\ 1101 = 0x11D$; index = 1'b0; byte offset = 2'b00

Check hit/miss?

Of course we get a miss here, bring the entire line into the second entry with index 1'b0

b. Load 0x8E9

Address partitioning

0xFE2 = 12'b1000 1110 1001:

where tag = $9'b1\ 0001\ 1101 = 0x11D$; index = 1'b0; byte offset = 2'b01

Check hit/miss

We have load contents into index 1'b0, and tag matches, we get a hit. Then load byte from byte=2'b01

Some cache line might be replaced then

3. Load byte at 0xDF7

Address partitioning

0xDF9 = 12'b1101 1111 0111:

where tag = $9'b1\ 1011\ 1110 = 0x1BE$; index = 1'b1; byte offset = 2'b01

heck hit/miss?

Valid is 0, it's a miss. Bring the entire line into the first empty entry with index=1'b1

4. Load byte at 0xAB8

Address partitioning

0xAB9 = 12'b1010 1011 1001:

where tag = $9'b1\ 0101\ 0111 = 0x157$; index = 1'b0; byte offset = 2'b01

Check hit/miss ?

Valid at index 1'b0 but tag doesn't match, it's a miss. Evict the cache line (oldest), in this case, it's entry0 in index0 Load from 0xAB8, and put it in the cache line

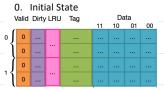

Set-Associative Cache Summary

Basically somewhere in between direct-mapped and fully associate $% \left(1\right) =\left(1\right) \left(1\right) \left($

- Instead of constrain location of data in cache to a certain cache line. The index navigates to several sets.
- For a 4-way set-associative cache, that cache allows storing 4 data with the same index

In addition to being a trade-off between direct-mapped and fully associative cache, this placement policy also features

- Pros: Allows flexibility of placement policies
- Cons: Still suffers from conflict misses

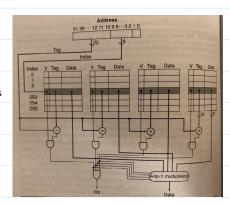

2. Read Byte 0x8E8 and then read 0x8E9
Valid Dirty LRU Tag Data

3. Read Byte 0xDF7
Valid Dirty LRU Tag Data
11 10 01 00

0 1 0 0 0x11C
1 0 0 1 0x11B
1 0 ... 1

5. Comparisons between Cache placement policies

0. Terminology Recap

- 0. Valid
- When start a new program, caches doesn't have valid information for this program
- Valid bit is the indicator to tell if each entry is valid for this program. 1 for valid, and 0 for non-valid

A. Tag

- Every line the cache has a tag which helps identify if the memory address that we are trying to access is stored in cache
- To check if our address matches a given line, we need to verify: (assume the index is good)
 - o Valid bit is 1
 - o Tag in cache is equal to tag in address

B. Write through vs. Write-back

- Write-through
 - o Write to the cache and the memory at the same time
 - Pros: Simple to implement
 - Cons: Write to memory will take longer, and increase the traffic to the memory
- Write-back
 - o Write data in caches, and set the dirty bit to 1 (additional data needed)
 - o When this line gets evicted from the cache, write it to memory
 - Pros: Lower traffic to memory, because you may write to something multiple times before you evict it from the cache
 - Cons: Additional control logics

C. Write allocate vs No write-allocate

- Write-allocate
 - On a write miss, you bring the line into the cache, and then update the line
- . No write-allocate
 - o On a write miss, do not bring the line into the cache, you only update memory

1. Comparison

Possible location A spec		Fully Associative	Direct Mapped	A specific line of data can be stored at only one index of the cache (but there should be multiple lines in each index, #ways > 1)	
		A specific line of data can be stored in any line of the cache	A specific line of data can only be stored in one index of the cache		
	Address Partitioning	• Tag • Byte (word offset)	Tag Index: for the ONLY slot Byte/word offset	Tag Index: for possible slots (# of "ways") Byte/word offset	
	Replacement policy	Flexible, user need to choose one accordingly	If the line you want to store the data in is already occupied, then you evict that line and load new data in. No option for replacement policy	Flexible, user need to choose one accordingly	

2. 3Cs for misses

- Compulsory Miss
 - $\circ \hspace{0.1in}$ Caused by the first access to a block that has never been in the cache
- Capacity Miss
 - Caused when the cache cannot contain all the blocks needed during the execution of a program
 - o Occurs when blocks were in the cache, replaced, and later retrieved
- Conflict Miss
 - o Occurs in set-associative or direct mapped caches when multiple blocks compete for the same set
 - Never appear in a fully-associative cache
